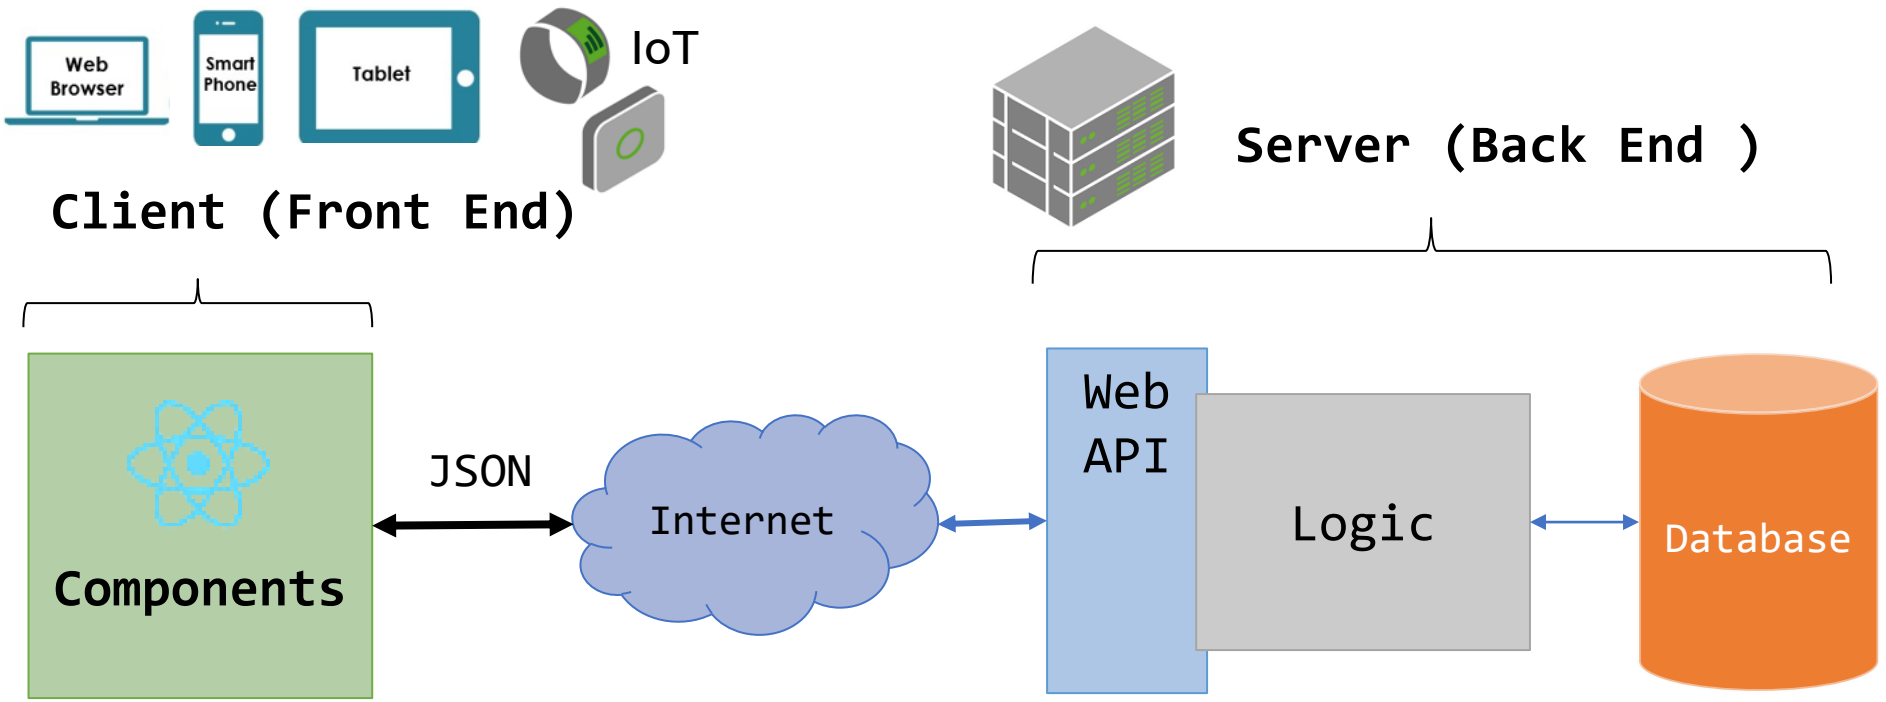
What is React?

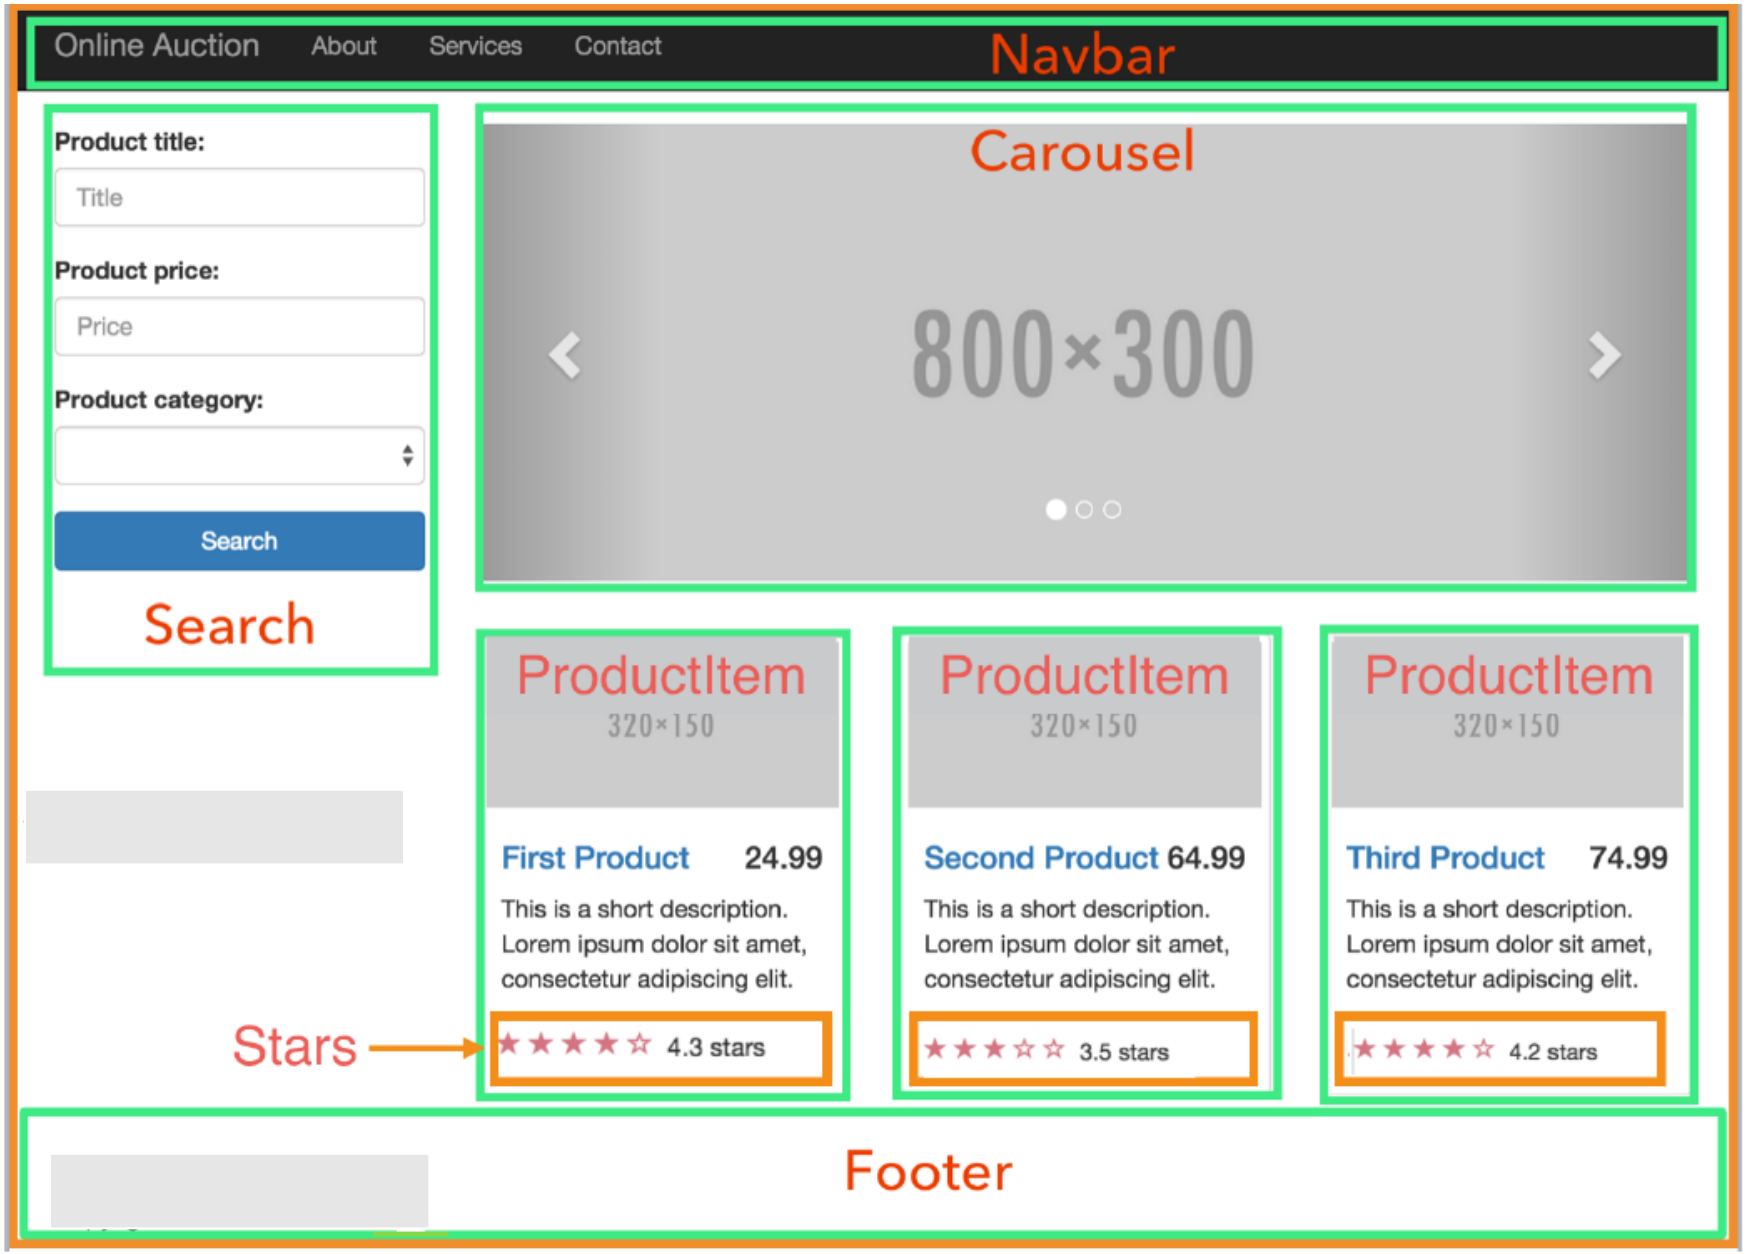
- React is an open-source JavaScript library for building **components-based user interfaces (UI)**
  - UI is **composed** of small reusable **components**
  - A component encapsulates **UI elements** and the **behavior** associated with them
- Ease creating a Single Page Application (SPA)
  - SPA is a Web app that load a single HTML page and **dynamically loads components** as the user interacts with the app
- Open-sourced by Facebook mid-2013 - https://reactjs.org/
- Competing with Angular http://angular.io and Vue.js https://vuejs.org/

Components of Single Page Application (SPA)

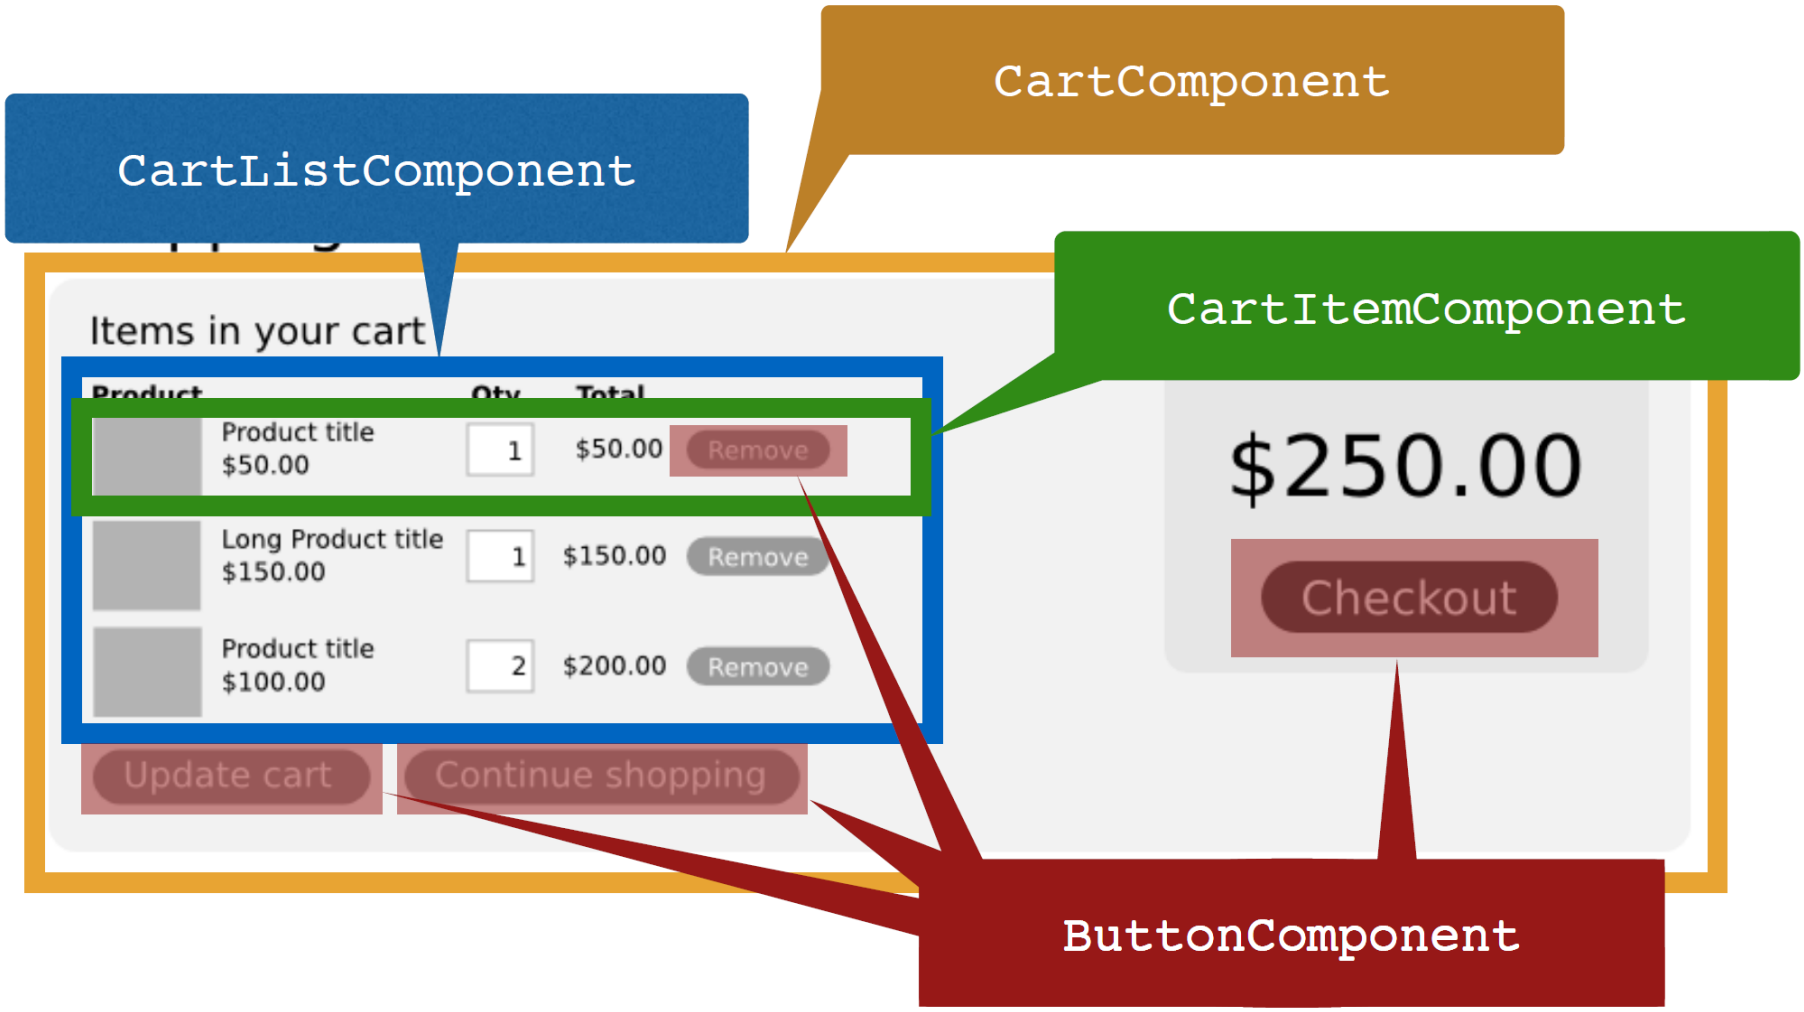
- A Single-Page Application (SPA) has **1 main shell page** and **multiple UI components loaded** in response to user actions



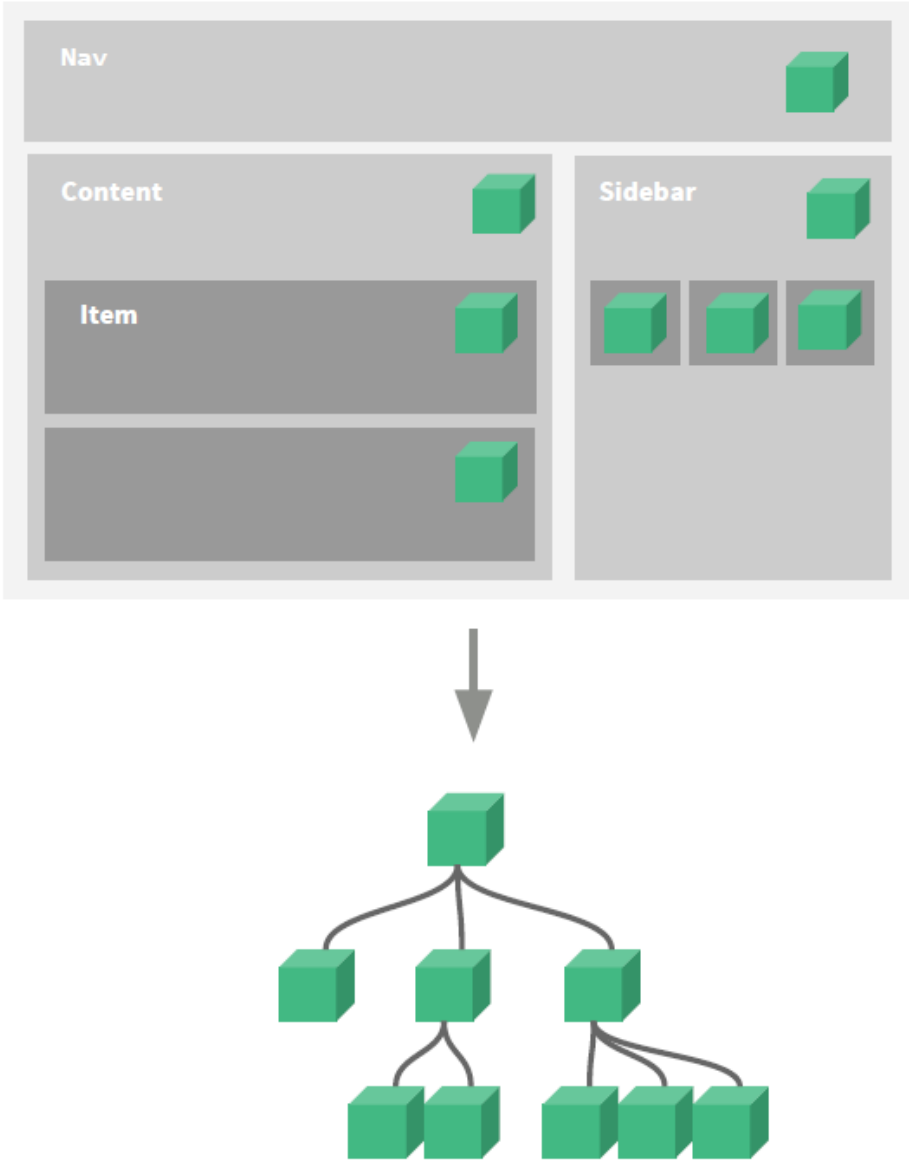
An app = a composition of components



An app = a tree of components



React Components



Getting started

- Install latest **Node.js** https://nodejs.org/en/
- Download **VS Code** https://code.visualstudio.com/
- Create an empty folder (with no space in the name use **dash -** instead)
- Create a react app

```
npx create-react-app .
```

- Run the app

```
npm start
```

React Component

- A React App is composed of self-contained and often reusable **components**
- A ***component***:
  - Return **HTML *elements*** to provide the UI
  - Encapsulate **state** (internal component data) and **functions** to ***handle events*** raised from the UI elements
- Component = UI + display logic
- Components allows creating new ‘HTML tags’

React = A declarative component-based programming model

- UI is built using JavaScript functions
  - Each function define a piece the app's UI programmatically
  - As state changes the UI automatically updates (Reactive UI)
    - without imperatively mutating UI views

How to define a piece of UI?

UI is **composed** of small reusable **components**

UI Component = a **function**:

- Takes some inputs and emits a piece of UI
- Function that converts the state (i.e., app data) into UI

- **UI = f(state) : UI is a visual representation of state**
  (e.g., display a tweet and associated comments)

- **State changes trigger automatic update of the UI**

Component Example

- Create a **Welcome** component
  - Returns **JSX** : an HTML-like syntax to define the component UI
  - Can accept a parameter called ***props***
  - Component name must start with a capital letter
  - **props** are read-only

```
import React from "react";
function Welcome(props) {
    return (<h1>Welcome to {props.appName}</h1>);
}
export default Welcome;
```

You can embed JavaScript expressions in JSX

- Use the **Welcome** component

```
<Welcome appName='React Demo App' />
```

What is JSX?

- React uses JSX (JavaScript XML) syntax to describe the component's UI
- Embraces the fact that rendering logic is inherently coupled with other UI
- JSX allows us to write HTML like syntax which gets transformed to JavaScript objects

JSX

```
const element = (
  <h1 className="greeting">
    Hello, world!
  </h1>
);
```

JavaScript

```
const element = React.createElement(
  'h1',
  {className: 'greeting'},
  'Hello, world!'
);
```

It's just JavaScript!!

Props destructuring

- In a **react** component you can destructure props into variables

```
function UserInfo(props) {
    return (
        <div>
            First Name: {props.firstName}
            Last Name: {props.lastName}
        </div>
    );
}
```

Becomes

```
function UserInfo({ firstName, lastName }) {
    return (
        <div>
            First Name: {firstName}
            Last Name: {lastName}
        </div>
    );
}
```

Rendering a List of items (with .map())

Lists are handled using **.map** array function

```
function FriendsList({friends}) {
  return <ul>
           {friends.map( (friend, i) =>
              <li key={i}>{friend}</li>
           )}
         </ul>
}
```

- Fatima
- Mouza
- Sarah

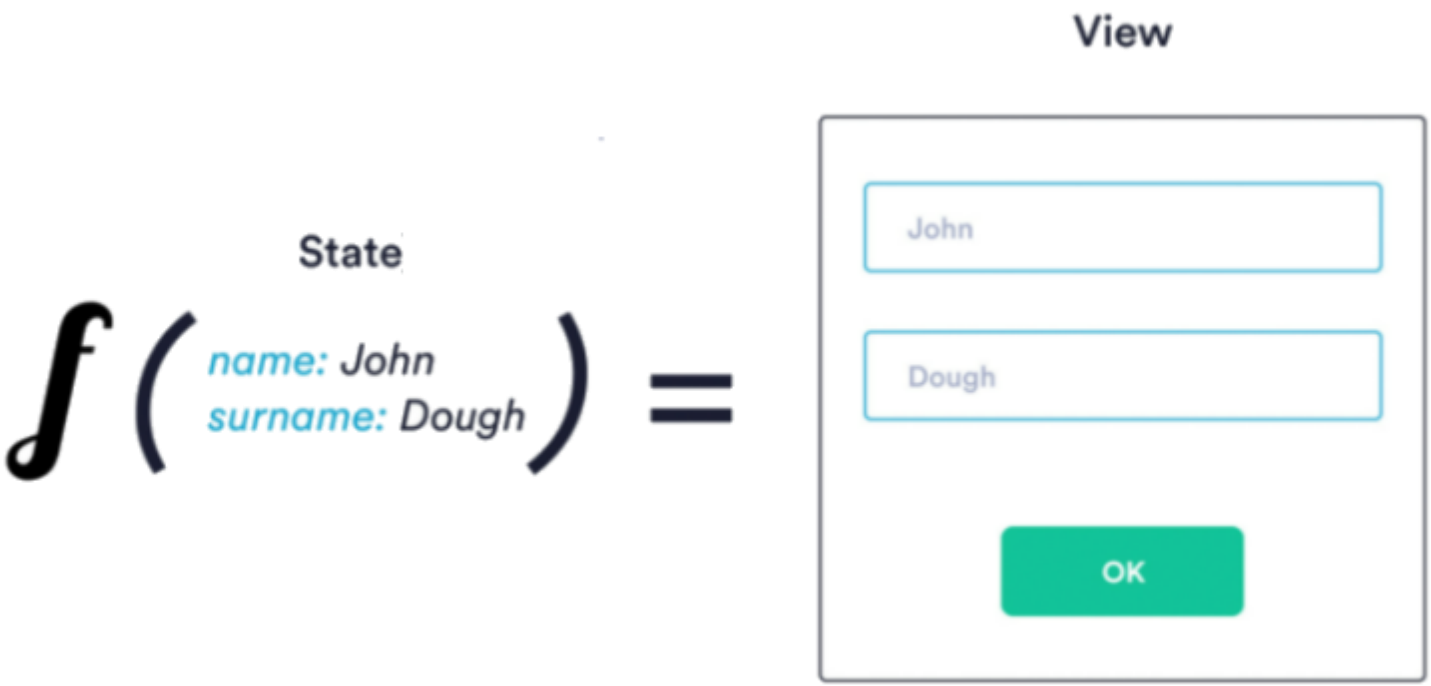
```
▼ <FriendsList>
  ▼ <ul>
      <li key="0">Fatima</li>
      <li key="1">Mouza</li>
      <li key="2">Sarah</li>
    </ul>
</FriendsList>
```

Key helps identify which items have changed, added or removed

- Use the **FriendsList** component

```
<FriendsList friends={['Fatima', 'Mouza', 'Sarah']}/>
```

State



Component State

- A component can store its own local data (**state**)
  - Private and fully controlled by the component
  - Can be passed as **props** to children
- Use `useState` hook to create a ***state variable*** and an **associated *function*** to update the state

```
const [count, setCount] = useState(0);
```

`useState` returns a state variable ***`count`*** initialized with 0 and a function ***`setCount`*** to be used to update it

  - Calling ***`setCount`*** causes React to **re-render the app components** and **update the DOM** to reflect the state changes

Never change the state directly by assigning a value to the state variable => otherwise React will NOT re-render the UI

State

- State = any value that can change overtime
- State variable must be declared using **useState** hook to act as **Change Notifiers**

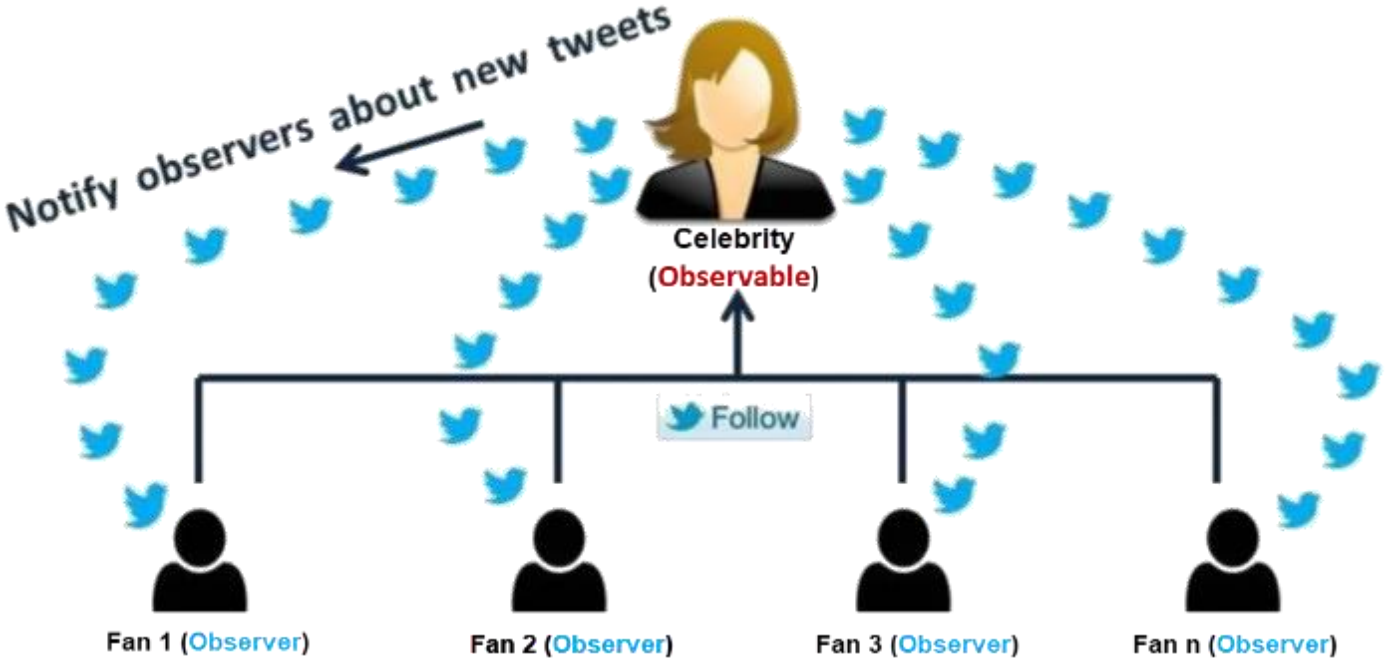
- They **are observed** by the React runtime
- Any change of a state variable will trigger the **re-rendering** of any functions that **reads** the state variable
- Both props and state changes trigger a render update

=> UI is **auto-updated** to reflect the updated app state

Observer Pattern at the heart of Jetpack Compose

Observer Pattern Real-Life Example: A celebrity who has many fans on Tweeter

- Fans want to get all the latest updates (posts and photos)
- Here fans are **Observers** and celebrity is an **Observable** (analogous **state variable in React**)
- **A State variable** is an **observable data holder**: React runtime **observes its changes** and updates the Ul accordingly



Imperative UI vs. Declarative UI

- Imperative UI – manipulate DOM to change its internal state / UI

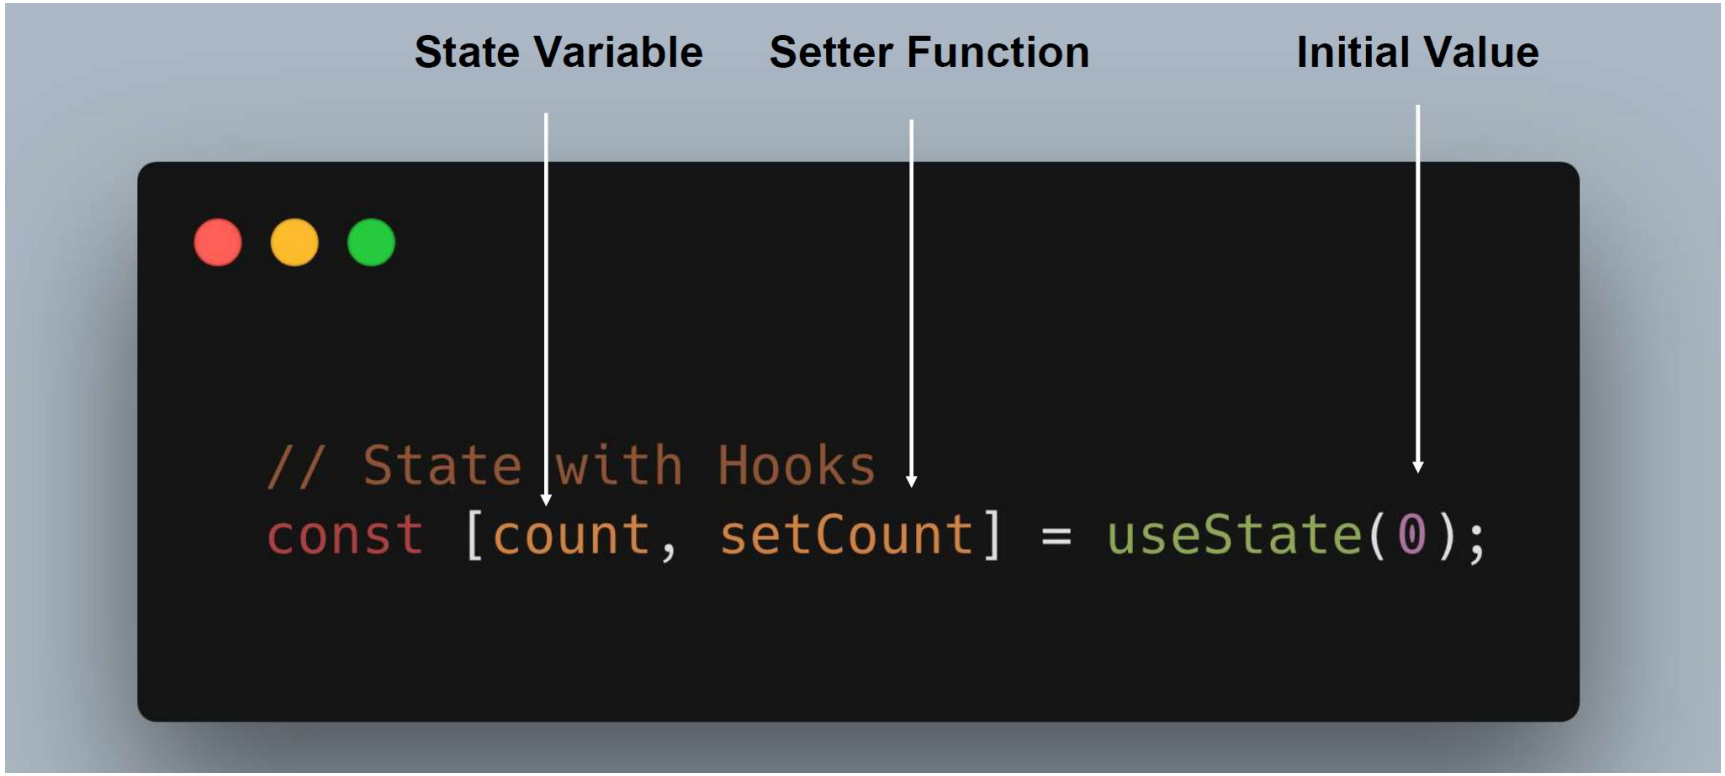
```
document.querySelector('#bulbImage').src = 'images/bulb-on.png';
document.querySelector('#switchBtn').value = "Turn off";
```

UI in React is immutable

- In react you should NOT access/update UI elements directly (as done in the imperative approach)
- Instead update the UI is by updating the state variable(s) used by the UI elements – this triggers automatic UI update
  - E.g., change the bulb image by updating the ***isBulbOn*** state variable

```
<input type="button"
       value= {isBulbOn ? "Turn off" : "Turn on"}
       onClick={() => setIsBulbOn(!isBulbOn)} />
```

useState Hook



Component with State + Events Handling

```
import React, { useState } from "react";

function Counter(props) {
    const [count, setCount] = useState(props.startValue);
    const increment = () => { setCount(count + 1); };

    const decrement = () => { setCount(count - 1); };

    return <div>
            Count: {count}
            <button type="button" onClick={increment}>+</button>
            <button type="button" onClick={decrement}>-</button>
        </div>
}
export default Counter;
```

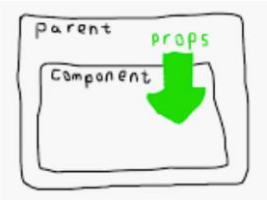
Count: 4 + -

Handling events is done the way events are handled on DOM elements

- Use the **Counter** component

```
<Counter startValue={3}/>
```

Uni-directional Data Flow: Props vs. State



- **Props** = data passed to the child component from the parent component

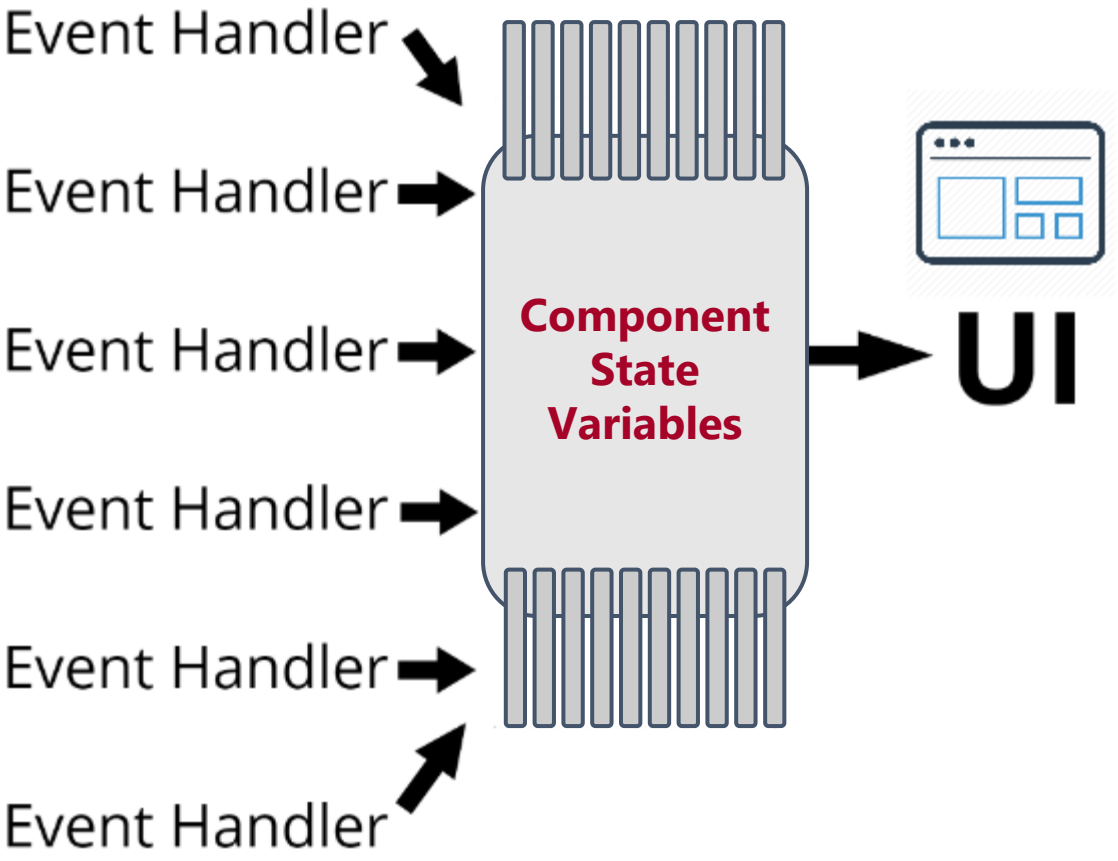
- **Props** parameters are **read only**

- **State** = internal data managed by the component (cannot be accessed and modified outside of the component)

- **State** variables are **Private** and **Modifiable** inside the component only (through **set** functions returned by useState)

👍**React automatically re-render the UI whenever state or props are updated**

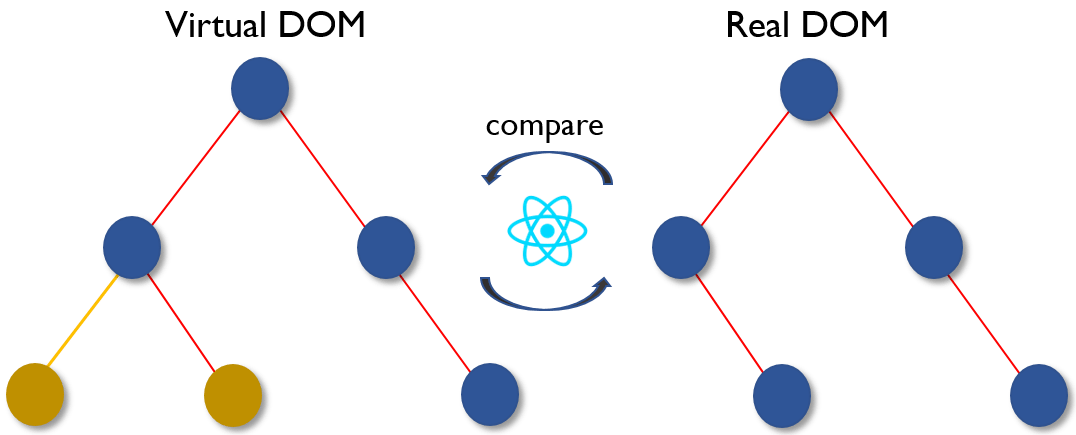
Event Handlers update the State and Reacts updates the UI



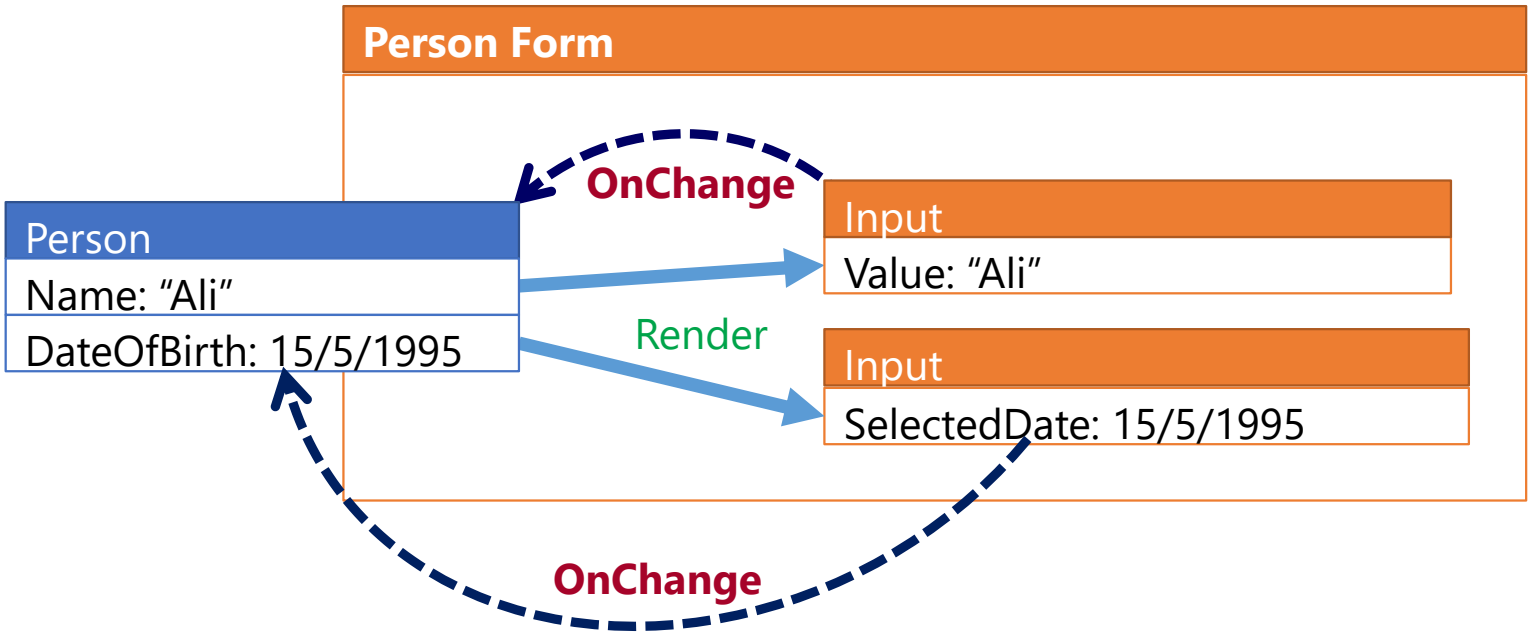
Every place a state variable is displayed is guaranteed to be auto-updated

Virtual DOM

- Virtual DOM = Pure JavaScript lightweight DOM, totally separate from the browser's slow JavaScript/C++ DOM API
- Every time the component **updates its state** or **receives new data via props**
  - A new virtual DOM tree is generated
  - New tree is **diffed** against old…
  - …producing a minimum set of changes to be performed on real DOM to bring it up to date



Unidirectional Data Flow in Forms



Common Events: `onClick - onSubmit – onChange`

Forms with React

Form UI

```
<form onSubmit={handleSubmit}>
    <input
        name="email"
        type="email" required
        value={values.user}
        onChange={handleChange} />
    <input
        name="password"
        type="password" required
        value={values.password}
        onChange={handleChange} />
    <input type="submit" />
</form>
```

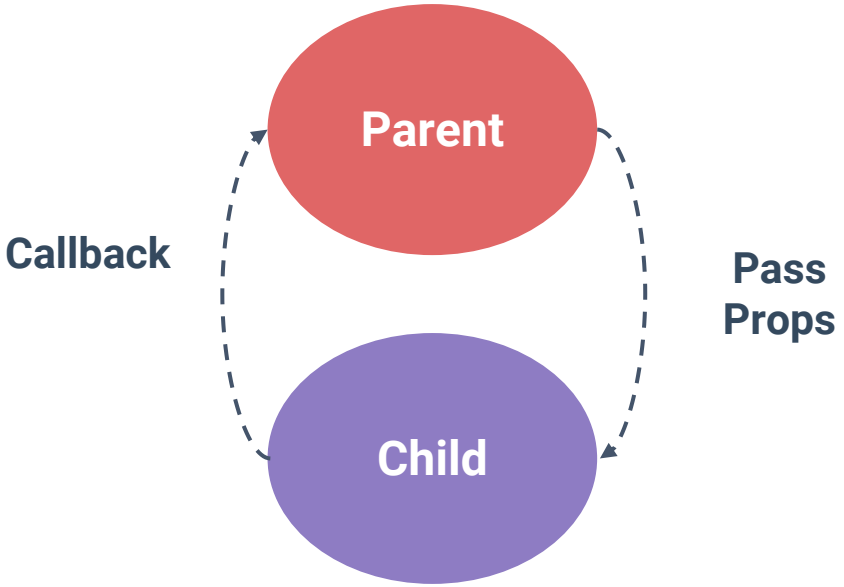
Form State and Event Handlers

```
const [values, setValues] = useState({ email: "", password: "" });

const handleChange = e => {
    const name = e.target.name;
    const value = e.target.value;
    //Merge the object before change with the updated property
    setValues({ ...values, [name]: value });
};

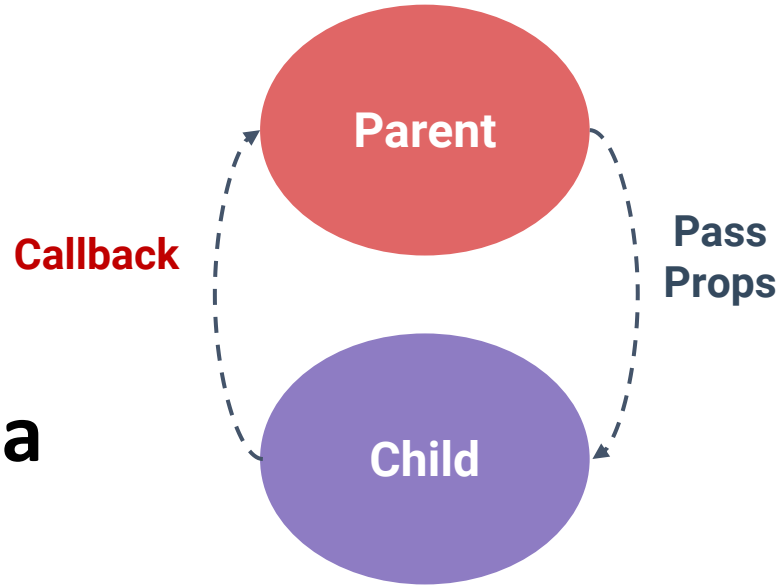
const handleSubmit = e => {
    e.preventDefault();
    alert(JSON.stringify(values));
};
```

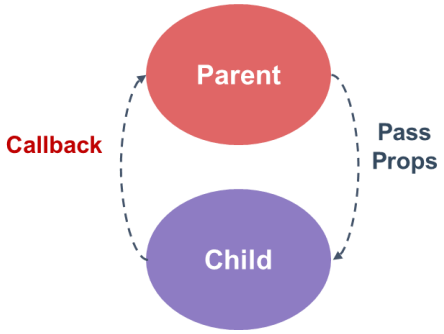
Components Communication



Composing Components

- Components are meant to be used together, most commonly in parent-child relationships.
- Parent passes data down to the child via **props**
- The child notify its parent of **a state change via callbacks** (a parent must pass the child a callback as a parameter)





Parent-Child Communication

Parent

```
<Counter startValue={3}
         onChange={count => console.log(`Count from the child component: ${count}`)}/>
```

Child

```
function Counter(props) {
    const [count, setCount] = useState(props.startValue);

    const increment = () => {
        const updatedCount = count + 1;
        setCount(updatedCount);
        props.onChange(updatedCount);
    };

    return <div>
        Count: {count}
        <button type="button" onClick={increment}>+</button>
    </div>
}
```

React Hooks

useEffect

useContext

What is Hook?

- A Hook is a special function that lets you “hook into” React features
- **useState**: creates a state variable
- **useEffect**: allows a running a function to execute some code at a specific time during the component lifecycle
  - when the component is first mounted to the DOM
  - every time a particular state variable changes
- **useContext**: allows providing and consuming ‘global’ variables and functions

useEffect – Executes code during Component Life Cycle

- **Initialize state data** when the component loads

```
useEffect(() => {
    async function fetchData() {
        const url = "https://api.github.com/users";
        const response = await fetch(url);
        setUsers( await response.json() ); // set users in state
        fetchData();
}, [ ]); // pass empty array to run this effect once when the component is first mounted to the DOM.
```

- **Executing a function every time a state variable changes**

```
useEffect(() => {
    async function fetchData() {
        const url = `https://hn.algolia.com/api/v1/search?query=${query}`;
        const response = await fetch(url);
        const data = await response.json();
        setNews(data.hits);
    }
    fetchData();
}, [query]);
```

If 2nd parameter is not set then the useEffect function will run on every re-render

useContext – Define global variables and functions

1. **Create a context** (i.e., a global container to provide global variables and functions available to all components)

```
import React from 'react';
const UserContext = React.createContext();
export default UserContext;
```

2. **Provider places global variables / functions in the context**

```
import UserContext from './components/UserContext';
function App() {
   return (
     <UserContext.Provider value={ user }>
            <Welcome appName='React Demo App'/> …
      </UserContext.Provider>
   );
}
```

3. **Consumer access the global variables / functions in the context**

```
import React, {useContext} from "react";  import UserContext from './UserContext';
export default function Welcome() {
    const user = useContext(UserContext);
    return <div>You are login as: {user.username}</div>;
}
```

React Tools and Component Libraries

- **React Dev Tools**
- **React Components Libraries**

React Dev Tools

- React Dev Tools

React Component Libraries

- **Material-UI**: React components with Material Design

https://mui.com/

- **Grommet Components**

https://v2.grommet.io/components

- **Blueprint**: React-based UI toolkit

https://blueprintjs.com/

- **Fluent UI React Components**

https://react.fluentui.dev/

Summary

- Decompose UI into self-contained and often reusable components

  - UI = Composition of Components

- Why React:
  - Component-based
  - Virtual DOM
  - Declarative
- React uses JSX (JavaScript Extension) syntax to define component's UI
